

# Dealing with NGS data: Differential Expression 

Club Moderators: Elton Vasconcelos and Eilidh Ward

## Important steps on NGS data analysis workflow

Software packages for DE analysis

| Method | Version | Reference | Normalization ${ }^{\text {a }}$ | Read count distribution assumption | Differential expression test |
| :---: | :---: | :---: | :---: | :---: | :---: |
| edgeR | 3.0.8 | [4] | TMM/Upper quartile/RLE (DESeq-like) None (all scaling factors are set to be one) | Negative binomial distribution | Exact test |
| $\begin{aligned} & \text { DESeq } \\ & \text { baySeq } \end{aligned}$ | $\begin{aligned} & 1.10 .1 \\ & \\ & 1.12 .0 \end{aligned}$ | $\text { [ } \underline{5}]$ $\text { [ } \underline{6} \text { ] }$ | DESeq sizeFactors $\text { Scaling factors (quantile } / \mathrm{TMM} / \text { total) }$ | Negative binomial distribution <br> Negative binomial distribution | Exact test \| <br> Assesses the posterior probabilities of models for differentially and non-differentially expressed genes via empirical Bayesian methods and then compares these posterior likelihoods |
| NOIseq | 1.1.4 | [7] | RPKM/TMM/Upper quartile | Nonparametric method | Contrasts fold changes and absolute differences within a condition to determine the null distribution and then compares the observed differences to this null |
| SAMseq <br> (samr) | 2.0 | [ 8] | SAMseq specialized method based on the mean read count over the null features of the data set | Nonparametric method | Wilcoxon rank statistic and a resampling strategy |
| Limma | 3.14 .4 | [9] | TMM | voom transformation of counts | Empirical Bayes method |
| Cuffdiff 2 <br> (Cufflinks) | $\begin{aligned} & 2.0 .2- \\ & \text { beta } \end{aligned}$ | [10] | Geometric (DESeq-like)/quartile/classic-fpkm | Beta negative binomial distribution | $t$-test |
| EBSeq | 1.1.7 | [11] | DESeq median normalization | Negative binomial distribution | Evaluates the posterior probability of differentially and non-differentially expressed entities (genes or isoforms) via empirical Bayesian methods |

${ }^{\mathrm{a}}$ In case of availability of several normalization methods, the default one is underlined.
$\rightarrow$ Important Output Metrics: $\log _{2}(\mathrm{FC}), \mathrm{p}$-value and FDR provided in most output files

## The DESeq2 model

- Perform a "median of ratios" normalization to correct for library size and RNA composition bias (counts divided by sample-specific size factors determined by median ratio of gene counts relative to geometric mean per gene);
- Use shrinkage estimation for dispersions and fold changes because small numbers of replicates make it impossible to estimate within-group variance reliably;
- Fit negative binomial generalized linear models for each gene and uses the Wald test for significance testing.

## Prepare the data for DESeq2 analysis

| countData: a matrix of non-negative integers |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| - | normal.rep1 * | normal.rep2 | normal.rep3 | tumor.rep1 | tumor.rep2 | tumor.rep3 | \% |
| ENSG00000283047 | 0 | 0 | 0 | 1 | 1 | 0 |  |
| ENSG00000283023 | 1 | 1 | 1 | 0 | 0 | 3 |  |
| ENSG00000280341 | 0 | 0 | 1 | 0 | 1 | 1 |  |
| ENSG00000279442 | 0 | 2 | 0 | 0 | 0 | 0 |  |
| ENSG00000237299 | 0 | 0 | 0 | 3 | 0 | 3 |  |
| ENSG00000233408 | 0 | 0 | 0 | 0 | 0 | 1 |  |
| ENSG00000215268 | 1 | 0 | 1 | 0 | 0 | 0 |  |
| ENSG00000230471 | 0 | 0 | 0 | 0 | 0 | 1 |  |
| ENSG00000231565 | 0 | 0 | 0 | 2 | 1 | 2 |  |

[^0]colData: a DataFrame with at least a single column. Rows of colData correspond to columns of countData.

|  | condition |
| :--- | :--- |
| normal.rep1 | normal |
| normal.rep2 | normal |
| normal.rep3 | normal |
| tumor.rep1 | tumor |
| tumor.rep2 | tumor |
| tumor.rep3 | tumor |

design: a formula expressing the variables which will be used in modelling.

## The main three steps of running DESeq2

1. Create a DESeqDataSet object from input. Please note that the colnames of countData must be identical to the rownames of colData.
keep = rowSums(count.data) >= 1
count.data.keep = count.data[keep,])
dds <- DESeqDataSetFromMatrix(countData = count.data.keep, colData = metadata, design $=\sim$ condition)
2. Perform the differential expression analysis.
dds <- DESeq(dds, fitType = "local")
3. Extract a results table.
res <- results(dds, contrast=c("condition", "tumor", "normal"))
write.table(res[order(res\$padj),], file="resultsDESeq2.tsv", sep = "\t", quote=F, col.names=NA)
